# Unipotent completion

For  $F$  a field of characteristic zero and  $\Gamma$  a finitely generated discrete group, have group algebra  $F\Gamma$ , its augmentation  $\epsilon : F\Gamma \rightarrow F$  and its **augmentation ideal**  $J = \ker\{\epsilon : F\Gamma \rightarrow F\}$ . The  $J$ -adic completion of  $F\Gamma$  is

$$F\Gamma^\wedge : \varprojlim_n F\Gamma/J^n.$$

This is a complete Hopf algebra.

## Unipotent Completion

The set of  $F$ -points of the **unipotent completion** of  $\Gamma$   $F$  is the prounipotent group

$$\Gamma^{\text{un}}(F) = \{\text{group-like elets of } F\Gamma^\wedge\} = \{x \in 1 + J^\wedge : \Delta x = x \otimes x\}.$$

## Example: completion of a free group

If  $\Gamma$  is the free group  $\Gamma = \langle u, v \rangle$  and  $ad - bc \neq 0$ , then

$$\theta : F\Gamma^\wedge \xrightarrow{\cong} F\langle\langle X, Y \rangle\rangle$$

is a (complete) Hopf algebra isomorphism when

$$\theta(u) = \exp U \text{ and } \theta(v) = \exp V$$

where  $U, V \in \mathbb{L}(X, Y)^\wedge$  and

$$U \equiv aX + bY \text{ and } V \equiv cX + dY \pmod{\mathcal{J}^2}.$$

Theta induces an isomorphism  $\Gamma^{\text{un}}(F) \xrightarrow{\cong} \exp \mathbb{L}(X, Y)^\wedge$

# Integral base points

$\mathbb{P}^1 - \{0, 1, \infty\}$  has no points over  $\mathbb{Z}$ , and  $\mathbb{P}^1$  has only 6 everywhere non-zero tangent vectors over  $\mathbb{Z}$ :

These tangent vectors are  $\partial/\partial z \in T_0\mathbb{P}^1$  and its translates under  $\text{Aut}(\mathbb{P}^1, \{0, 1, \infty\})$ .

# Real blow-up

# Drinfeld Associator

The **Drinfeld associator**  $\Phi(Y, Z) \in \mathbb{C}\langle\langle Y, Z \rangle\rangle$  is the regularized value of the parallel transport, along the unit interval, of the *KZ*-connection

$$\nabla f = df - f\omega$$

where

$$\omega = \frac{dz}{z} Y + \frac{dz}{z-1} Z \in H^0(\Omega_{\mathbb{P}^1}^1(\log\{0, 1, \infty\}) \otimes \mathbb{L}(Y, Z).$$

Its coefficients are multi-zeta numbers:

$$\begin{aligned} \Phi(Y, Z) = & 1 + \zeta(2)[Y, Z] - \zeta(3)[Y, [Y, Z]] + \zeta(1, 2)[[Y, Z], Z] \\ & - \zeta(4)[Y, [Y, [Y, Z]]] - \zeta(1, 3)[Y, [[Y, Z], Z]] \\ & + \zeta(1, 1, 2)[[[Y, Z], Z], Z] + \frac{1}{2}\zeta(2)^2[Y, Z]^2 + \dots \end{aligned}$$

# Fundamental groupoid

The Drinfeld associator defines a functor from the fundamental groupoid of  $\mathbb{P}^1 - \{0, 1, \infty\}$  to the group-like elements of

$$\mathbb{C}\langle\langle X_0, X_1 \rangle\rangle \\
\cong \mathbb{C}\langle\langle X_0, X_1, X_\infty \rangle\rangle / (X_0 + X_1 + X_\infty).$$

# Punctured elliptic curves

Want to study the motivic structure on the unipotent completion of a punctured elliptic curve.

- Suppose  $E = (E, 0)$  is an elliptic curve over  $\mathbb{C}$ .
- Set  $E' := E - \{0\}$
- For  $x \in E'$ , have  $\pi_1(E', x)$ , a free group of rank 2.

Likewise, for  $\vec{v} \in T_{\text{id}}E - \{0\}$ , we have  $\pi_1(E', \vec{v})$

# The fundamental torsor

We would like to generalize the genus 0 story to genus 1. But in genus 1, there are many elliptic curves. So we consider all at once:

$$\mathcal{E} \rightarrow \mathcal{M}_{1,1}$$

is the universal punctured elliptic curve. Over  $\mathcal{E}'$ , the universal punctured elliptic curve, we have the torsor

$$\mathcal{P} \rightarrow \mathcal{E}'$$

whose fiber over  $[E, x]$  is the unipotent completion of  $\pi_1(E', x)$ .

# The universal elliptic curve

To describe  $\mathcal{P}$ , we need an explicit description of  $\mathcal{E}$ . It is the orbifold quotient

$$\mathcal{E} = (\mathrm{SL}_2(\mathbb{Z}) \ltimes \mathbb{Z}^2) \backslash (\mathbb{C} \times \mathfrak{h})$$

where

$$(m, n) : (\xi, \tau) \mapsto (\xi + m\tau + n, \tau)$$

and

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} : (\xi, \tau) \mapsto (\xi/(c\tau + d), (a\tau + b)/(c\tau + d)).$$

# The Jacobi form $F(\xi, \eta, \tau)$

A certain Jacobi modular form  $F$  is fundamental in writing down the connection on  $\mathcal{P}$ . Geometrically,  $F$  is a section of a line bundle over the total space of

$$\bar{\mathcal{E}} \times_{\overline{\mathcal{M}}_{1,1}} \bar{\mathcal{E}} \rightarrow \overline{\mathcal{M}}_{1,1}.$$

whose divisor is

$$\iota^* \Delta - Z_1 - Z_2$$

where  $\iota^* \Delta$  is the graph of the elliptic involution  $\iota : x \mapsto -x$  and  $Z_j$  is the locus  $z_j = 0$ , where  $(z_1, z_2)$  are the fiber coordinates.

# Formula for $F$

$F$  is a meromorphic function on  $\mathbb{C} \times \mathbb{C} \times \mathfrak{h}$ , first defined by Kronecker (1881) and rediscovered by Zagier (1991):

$$\begin{aligned} F(\xi, \eta, \tau) &= \frac{\theta'(0; \tau)\theta(\xi + \eta; \tau)}{\theta(\xi, \tau)\theta(\eta, \tau)} \\ &= \frac{1}{\xi} + \frac{1}{\eta} - 2 \sum_{r,s=0}^{\infty} (2\pi i)^{1+\max\{r,s\}} \left(\frac{\partial}{\partial \tau}\right)^{\min\{r,s\}} G_{|r-s|+1}(\tau) \frac{\xi^r}{r!} \frac{\eta^s}{s!}, \end{aligned}$$

where  $G_{\text{odd}} = 0$  and

$$G_{2m}(\tau) = -\frac{B_{2m}}{4m} + \sum_{n=1}^{\infty} \sigma_{2m-1}(n) q^n$$

with  $q = \exp(2\pi i\tau)$ . The function  $F$  is modular in  $\tau$  and is elliptic in  $\xi$  and  $\eta$ .

# The Levin-Racinet connection

Denote the group-like elements of  $\mathbb{C}\langle\langle T, A \rangle\rangle$  by  $\mathcal{P}$  and its Lie algebra  $\mathbb{L}(T, A)^\wedge$  by  $\mathfrak{p}$ . Then the 1-form

$$\omega = 2\pi i A \frac{\partial}{\partial T} dT + \psi + \nu \in H^0(\Omega_{\mathbb{C} \times \mathfrak{h}}^1) \hat{\otimes} \text{Der } \mathfrak{p}$$

defines a connection on  $\mathcal{P} \times \mathbb{C} \times \mathfrak{h} \rightarrow \mathfrak{h}$  by  $\nabla f = df + \omega f$ , where

$$\psi = 4\pi i \sum_{m \geq 1} \left[ \frac{G_{2m+2}(\tau)}{(2m)!} d\tau \sum_{\substack{j+k=2m+1 \\ j,k > 0}} (-1)^j [\text{ad}_T^j(A), \text{ad}_T^k(A)] \frac{\partial}{\partial A} \right]$$

and

$$\nu = \text{ad}_T F(\xi, \text{ad}_T / 2\pi i, \tau)(A) d\xi + \left( \frac{1}{\text{ad}_T} + \text{ad}_T \frac{\partial F}{\partial T}(\xi, \text{ad}_T / 2\pi i, \tau) \right)(A) d\tau.$$

Description of  $\mathcal{P}^{\text{DR}}$ 

The action of  $\text{SL}_2(\mathbb{Z}) \ltimes \mathbb{Z}^2$  on  $\mathbb{C} \times \mathfrak{h}$  can be lifted to this bundle. The quotient is, by definition,  $\mathcal{P}^{\text{DR}}$ . For  $\gamma \in \text{SL}_2(\mathbb{Z}) \ltimes \mathbb{Z}^2$  define

$$\gamma(u, \xi, \tau) = (\tilde{M}_\gamma(\xi, \tau)u, g(\xi, \tau))$$

where  $\tilde{M}_\gamma(\xi, \tau) = e^{-m \text{ad}_\tau}$  when  $\gamma = (m, n) \in \mathbb{Z}^2$  and, when  $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(\mathbb{Z})$ ,

$$\tilde{M}_\gamma(\xi, \tau) = M_\gamma(\tau) \circ \exp(c\xi \text{ad}_\tau / (c\tau + d))$$

where

$$M_\gamma(\tau) : \begin{cases} A & \mapsto (c\tau + d)^{-1}A + c\tau \\ T & \mapsto (c\tau + d)T \end{cases}$$

# Flatness and descent

## Theorem (Levin-Racinet)

- ① *The connection is invariant: for all  $\gamma \in \mathrm{SL}_2(\mathbb{Z}) \ltimes \mathbb{Z}^2$*

$$\gamma^* \omega = \mathrm{Ad}(\gamma) \omega - d\tilde{M}_\gamma \tilde{M}_\gamma^{-1}$$

- ② *The connection is flat:*

$$d\omega + \frac{1}{2}[\omega, \omega] = 0.$$

So the connection descends to a flat meromorphic connection on the principal  $\mathcal{P}^{\mathrm{DR}}$  bundle  $(\mathrm{SL}_2(\mathbb{Z}) \ltimes \mathbb{Z}^2) \backslash (\mathcal{P} \times \mathbb{C} \times \mathfrak{h})$  over  $\mathcal{E}$ .

On each 2-pointed elliptic curve  $(E_\tau, 0, x)$ , the connection restricts to the flat connection

$$\nabla = d + \text{ad}_T F(\xi, \text{ad}_T / 2\pi i, \tau)(A) d\xi.$$

Parallel transport induces a homomorphism

$$\pi_1(E'_\tau, x) \rightarrow \mathcal{P}$$

that is an isomorphism as

$$\mathbf{a} \mapsto 2\pi i A \text{ and } \mathbf{b} \mapsto 2\pi i \tau A - T \text{ mod } [\mathcal{P}, \mathcal{P}].$$

### Theorem (Rigidity)

*The flat bundles  $\mathcal{P}^{\text{DR}}$  and  $\mathcal{P}$  are isomorphic.*

# Outline

- 1 Preliminaries

  - Unipotent Completion
  - Review of genus 0 story
- 2 Genus 1 Story
  - Introduction
  - The Levin-Racinet connection
  - **Monodromy representation**
- 3 Mixed Elliptic Motives
  - Definition
  - Tannakian fundamental group
  - Generators and relations

# Introduction

Our goals are to:

- 1 find suitable integrally defined base points that are everywhere non-zero;
- 2 for these, compute the monodromy isomorphism

$$\pi_1(E'_o, x_o)^{\text{un}} \rightarrow \mathcal{P};$$

- 3 “compute” the corresponding monodromy representation

$$\pi_1(\mathcal{M}_{1,\vec{1}}, o) \rightarrow \text{Aut } \mathcal{P}.$$

To do this, we will localize the LR connection about  $E_o$ , which will turn out to be the first order Tate curve.

# Integral base points

The natural coordinate on  $\overline{\mathcal{M}}_{1,1}$  about the cusp is  $q := \exp(2\pi i\tau)$ . The fiber of  $\overline{\mathcal{E}} \rightarrow \mathcal{M}_{1,1}$  over the cusp  $q = 0$  is the nodal cubic. This can be identified with  $\mathbb{P}^1$  with  $0 \sim \infty$ . There is a unique parameter  $w$  on the nodal cubic that takes the value 1 at the identity.

- There are no integral points  $\text{Spec } \mathbb{Z} \rightarrow \mathcal{M}_{1,\overline{1}}$ .
- The only everywhere non-zero integral tangent vectors are  $\text{Spec } \mathbb{Z}[\epsilon]/(\epsilon^2) \rightarrow \mathcal{M}'_{1,\overline{1}}$  are  $\pm \frac{\partial}{\partial q} \pm \frac{\partial}{\partial w}$ .

Denote the fiber of  $\mathcal{E}$  over  $\partial/\partial q$  by  $E_{\partial/\partial q}$ . It is the first order Tate curve. As a base point we choose  $\vec{v} = \partial/\partial q + \partial/\partial w$ .

# Tangential base points

Since all of our base points will be tangential, we will restrict the torsor  $\mathcal{P}$  to the punctured relative tangent bundle of the identity section:

$$\mathcal{M}_{1,\vec{1}} \hookrightarrow \mathcal{E}'$$

This is the  $\mathbb{C}^*$ -bundle associated to the dual of the Hodge bundle over  $\mathcal{M}_{1,1}$ :

$$\mathcal{M}_{1,\vec{1}} = \{(E, \vec{v})\} / \text{isomorphism} = \mathrm{SL}_2(\mathbb{Z}) \backslash (\mathbb{C} \times \mathfrak{h})$$

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} : (\xi, \tau) \mapsto (\xi / (c\tau + d), (a\tau + b) / (c\tau + d))$$

# Topologists' picture

$$\begin{array}{ccc}
 \mathcal{M}_{1, \vec{1}} & \longrightarrow & \mathcal{E} \\
 & \searrow & \downarrow \\
 & & \mathcal{M}_{1, 1}
 \end{array}$$

# Restriction of LR-connection to $E_{\partial/\partial q}$

This is  $\nabla = d + \omega_0$ , where

$$\omega_0 = N_q \frac{dq}{q} + [T, A] \frac{dw}{w-1} + \left( \frac{\text{ad}_T}{e^{\text{ad}_T} - 1} \right) (A) \frac{dw}{w}.$$

where

$$N_q = A \frac{\partial}{\partial T} + \sum_{m=1}^{\infty} \frac{B_{2m}}{2m(2m-2)!} \left( \text{ad}_T^{2m-1}(A) - \sum_{\substack{j+k=2m-1 \\ j>k>0}} (-1)^j [\text{ad}_T^j(A), \text{ad}_T^k(A)] \frac{\partial}{\partial A} \right)$$

Set

$$R_0 = \left( \frac{\text{ad}_T}{e^{\text{ad}_T} - 1} \right) (A), \quad R_1 = [T, A], \quad R_\infty = \left( \frac{\text{ad}_T}{e^{-\text{ad}_T} - 1} \right) (A)$$

Note that  $R_0$  is the generating function for Bernoulli numbers.

# Fundamental group of $E'_{\partial/\partial q}$

Identify outer and inner circles to obtain  $E_{\partial/\partial q}$ . The diagram gives a well defined homomorphism  $\pi_1(E'_{\partial/\partial q}, \vec{v}) \rightarrow \mathcal{P}$  because of the **cylinder relation**:

$$e^T e(\lambda R_0) e^{-T} e(\lambda R_\infty) = 1$$

which holds for all  $\lambda \in \mathbb{C}$ .

# Monodromy computation

Define  $\widetilde{SL}_2(\mathbb{Z})$  to be the inverse image of  $SL_2(\mathbb{Z})$  in the universal covering group of  $SL_2(\mathbb{R})$ . It is an extension

$$0 \rightarrow \mathbb{Z} \rightarrow \widetilde{SL}_2(\mathbb{Z}) \rightarrow SL_2(\mathbb{Z}) \rightarrow 1.$$

and has presentation  $\langle S, U : S^2 = U^3 \rangle$ . It is isomorphic to  $B_3$ .

$\pi_1(\mathcal{M}_{1,1}, \vec{v})$  is isomorphic to  $\widetilde{SL}_2(\mathbb{Z})$ . It is generated by:

- 1 the Dehn twist about  $q = 0$ , which acts as  $\exp(2\pi i N_q)$ ;
- 2 any lift  $\sigma$  of  $\tau \mapsto -1/\tau$  to  $\widetilde{SL}_2(\mathbb{Z})$ , which acts via a formal series of iterated integrals of Eisenstein series, and acts via a representation of one of Manin's non-abelian modular symbols.

# Remarks

- 1 The condition that  $\exp(N_q) : \mathcal{P} \rightarrow \mathcal{P}$  preserve the image of  $\pi_1(E'_{\partial/\partial q}, \vec{v})$  and fix the image of  $\pi_1(\mathbb{P}^1 - \{0, 1, \infty\}, \partial/\partial w)$  appears to be strong. For example, it implies that  $N_q(\Phi(R_0, R_1))\Phi(R_1, R_0)$  must commute with  $\exp(2\pi i R_0)$ . Pollack and I are currently investigating whether this implies, for example, the double shuffle relations.
- 2 That the monodromy  $\Theta(\sigma) : \mathcal{P} \rightarrow \mathcal{P}$  preserves the image of  $\pi_1(E'_{\partial/\partial q}, \vec{v})$  appears to be deeper. This may impose relations on MZN, but more likely it will give a computation of Manin's non-abelian modular symbols of Eisenstein series in terms of MZN. If all periods of mixed Tate motives over  $\mathbb{Z}$  are MZNs, then (I believe) the coefficients of the Manin symbol will be MZNs.

  - Tannakian fundamental group
  - Generators and relations

# Informal description

A *mixed elliptic motive over  $\mathbb{Z}$*  should be a “motivic local system”  $\mathbb{V}$  of  $\mathbb{Q}$ -vector spaces over  $\mathcal{M}_{1,1}/\mathbb{Z}$  with a weight filtration  $W_\bullet$  that satisfies:

- 1 each weight graded quotient of  $\mathbb{V}$  is a sum of the simple local systems  $S^n\mathbb{H}(m)$ , where  $\mathbb{H} = R^1\pi_*\mathbb{Q}(0)$  and  $\pi : \mathcal{E} \rightarrow \mathcal{M}_{1,1}$  is the universal elliptic curve;
- 2 the fiber  $V_{\partial/\partial q}$  of  $\mathbb{V}$  over  $\partial/\partial q$  is in  $\text{MTM}(\mathbb{Z})$ .

A basic example of an Ind-object of  $\text{MEM}(\mathbb{Z})$  should be the local system consisting of the coordinate rings of the unipotent completions of the  $\pi_1(E', \vec{v})$

# Mixed elliptic motives

## Conjecture

There is a tannakian category  $\text{MEM}(\mathbb{Z})$  of mixed elliptic motives over  $\text{Spec } \mathbb{Z}$  that contains  $\text{MTM}(\mathbb{Z})$  as a full subcategory and satisfies:

- 1 There is a fiber functor  $\text{MEM}(\mathbb{Z}) \rightarrow \text{MTM}(\mathbb{Z})$  whose restriction to  $\text{MTM}(\mathbb{Z})$  is the identity.
- 2 There are realization functors, *Betti*, *Hodge*,  *$\ell$ -adic*,  *$\mathbb{Q}$ -de Rham*,... to  $\mathbb{Q}$ -local systems, VMHS, lisse  $\ell$ -adic sheaves,  $\mathbb{Q}$ -connections, ... over  $\mathcal{M}_{1,1}$  that commute with the fiber functor to  $\text{MTM}(\mathbb{Z})$ .
- 3 All weight graded quotients are direct sums of Tate twists of symmetric powers of  $\mathbb{H}$ .

# Outline

  - Unipotent Completion
  - Review of genus 0 story
- 2 Genus 1 Story
  - Introduction
  - The Levin-Racinet connection
  - Monodromy representation
- 3 Mixed Elliptic Motives
  - Definition
  - Tannakian fundamental group
  - Generators and relations

# Fundamental group of $\text{MEM}(\mathbb{Z})$

This will be a proalgebraic  $\mathbb{Q}$ -group that is a split extension

$$1 \rightarrow \mathcal{G} \rightarrow \pi_1(\text{MEM}) \rightarrow \pi_1(\text{MTM}) \rightarrow 1.$$

where  $\mathcal{G}$  (the “geometric fundamental group”) is an extension

$$1 \rightarrow \mathcal{U} \rightarrow \mathcal{G} \rightarrow \text{SL}_2 \rightarrow 1$$

with  $\mathcal{U}$  prounipotent. There will be Zariski dense reps:

$$\text{SL}_2(\mathbb{Z}) \rightarrow \mathcal{G}(\mathbb{Q}) \text{ and } \pi_1(\mathcal{M}_{1,1/\mathbb{Q}}) \rightarrow \pi_1(\text{MEM})(\mathbb{Q}_\ell).$$

Thus  $\mathcal{G}$  will be a quotient of the relative unipotent completion of  $\text{SL}_2(\mathbb{Z})$  and  $\pi_1(\text{MEM})$  will be a quotient of the  $\ell$ -adic relative unipotent completion of  $\pi_1(\mathcal{M}_{1,1/\mathbb{Q}})$ . The coordinate ring  $\mathcal{O}(\mathcal{G})$  will be an Ind object of  $\text{MTM}(\mathbb{Z})$ .

  - Definition
  - Tannakian fundamental group
  - **Generators and relations**

# The Lie algebra of $\mathcal{U}$

A computation (with Matsumoto) of the relative unipotent completion of  $\pi_1(\mathcal{M}_{1,1}/\mathbb{Q}, \partial/\partial q)$  implies that the Lie algebra  $\mathfrak{u}$  of  $\mathcal{U}$  (if it exists) has presentation of the form

$$\mathrm{Gr}_{\bullet}^W \mathfrak{u} = \mathbb{L}((\oplus_{m \geq 1} S^{2m-2} H(2m-1)) / (\rho_{f,n} : n \geq 1))$$

where  $f$  ranges over the cusp forms of  $\mathrm{SL}_2(\mathbb{Z})$ . Let  $e_{2m}$  be a highest weight vector of  $S^{2m-2} H(2m-1)$  with respect to the torus that is diagonal in the basis  $A, T$  of  $H$ . It has motivic weight  $-2m$ .

For  $m \geq 1$ , set

$$\epsilon_{2m} := \text{ad}_T^{2m-1}(A) - \sum_{\substack{j+k=2m-1 \\ j>k>0}} (-1)^j [\text{ad}_T^j(A), \text{ad}_T^k(A)] \frac{\partial}{\partial A}.$$

The homomorphism  $u \rightarrow \text{Der } \mathfrak{p}$  will take  $e_{2m}$  to  $\epsilon_{2m}$ . Relations satisfied by the  $e_{2m}$  will be satisfied by the  $\epsilon_{2m}$ .

# Modular symbols

The *modular symbol* associated to a cusp form  $f$  of  $SL_2(\mathbb{Z})$  of weight  $2m$  is the homogeneous polynomial

$$r_f(x, y) := \int_0^{i\infty} f(\tau)(x - \tau y)^{m-2} d\tau.$$

of degree  $2m - 2$ . The even bidegree part is

$$r_f^+(x, y) = (r_f(x, y) + r_f(x, -y))/2.$$

This can be generalized to Eisenstein series.

### Theorem (Pollack)

If  $m_j, n_j$  are positive integers satisfying  $2m_j + 2n_j = 2k - 2$ , then

$$\sum_j a_j [\epsilon_{2m_j+2}, \epsilon_{2n_j+2}] = 0 \text{ in Der } \mathfrak{p}$$

if and only if there is a modular form  $f$  of weight  $2k + 2$  such that

$$r_f^+(x, y) = \sum_j a_j (x^{2m_j} y^{2n_j} - x^{2n_j} y^{2m_j}).$$

- 1  $c(x^{2n} - y^{2n})$  is the period polynomial of  $G_{2n+2}$ . This gives the relation  $[\epsilon_2, \epsilon_{2n}] = 0$  for all  $n \geq 1$ .
- 2 From the Ramanujan  $\tau$  function:  $[\epsilon_{10}, \epsilon_4] - 3[\epsilon_8, \epsilon_6] = 0$

## Remark

Compare with results of:

- Schneps (2005): relates modular symbols of cusp forms to congruences between certain integral elements in  $\text{Der Gr}_{\bullet}^W \pi_1(\mathbb{P}^1 - \{0, 1, \infty\})^{\text{un}}$ .
- Gangl-Kaneko-Zagier (2006): Relations between double zeta values and period polynomials of cusp forms.

All three results should be manifestations of one result.
