Symmetric Matrices & the Spectral Theorem Recall: $S \not\equiv Symmetric$ if $S=S^T$ ($\Rightarrow square$)

Super-important example:

Eg:
$$S = \frac{1}{9} \begin{pmatrix} 5 - 8 & 10 \\ -8 & 11 & 2 \\ 10 & 2 & 2 \end{pmatrix}$$

[demo]: what do you notice about the eigenspaces?

Observation 0: for any vectors v and ω , $v \cdot (S\omega) = v^T S\omega = (STv)^T\omega = (Sv)^T\omega = (Sv) \cdot \omega$ $v \cdot (S\omega) = (Sv) \cdot \omega$

Observation 1:

Eigenvectors of S with different eigenvalues are orthogonal.

Proof: Say
$$S_{V_1} = \lambda_1 V_1$$
 $S_{V_2} = \lambda_2 V_2$ $\lambda_1 \neq \lambda_2$
 $V_1 \cdot (S_{V_2}) = V_1 \cdot (\lambda_2 V_2) = \lambda_2 V_1 \cdot V_2$
 $(S_{V_1}) \cdot V_2 = \lambda_1 V_1 \cdot V_2$

$$\lambda_{1}, \lambda_{2}, \lambda_{3} \Rightarrow (\lambda_{1}, \lambda_{2}) = 0$$

$$\lambda_{1}, \lambda_{2}, \lambda_{3} \Rightarrow (\lambda_{1}, \lambda_{2}) = 0$$

$$\lambda_{2}, \lambda_{3}, \lambda_{4} \Rightarrow \lambda_{3}, \lambda_{4} \Rightarrow \lambda_{5}, \lambda_{5} \Rightarrow \lambda$$

Observation 2:

All eigenvalues of S are real.

Proof: Say Sv=2v and 2 is not real.

Then $\lambda \neq \bar{\lambda}$. Conjugate eigenvalue: $S \bar{\nu} = \bar{\lambda} \bar{\nu}$.

Observation 1 => v·v=0. But

$$\Lambda = \begin{pmatrix} \pm^{\nu} \\ \pm^{i} \end{pmatrix} \qquad \underline{\Lambda} = \begin{pmatrix} \pm^{\nu} \\ \pm^{i} \end{pmatrix}$$

= |21/2+ ···+ |2/2>0

So this can't happen.

Fact: It S is symmetric and λ is an eigenvalue, then $AM(\lambda) = GM(\lambda)$.

(The proof requires ideas from abstract linear algebra)

Consequence: S is diagonalizable over the real numbers! Moreover, there is an orth-normal eigenbasis.

Eg:
$$S = \frac{1}{9} \begin{pmatrix} 5 - 8 & 10 \\ -8 & 11 & 2 \\ 10 & 2 & 2 \end{pmatrix}$$
 $\rho(\lambda) = -(\lambda - 1)(\lambda + 1)(\lambda - 2)$

Eigenvectors:

Sometons:

$$\lambda = 1 \longrightarrow \omega_1 = \begin{pmatrix} 1 \\ 2 \\ -2 \end{pmatrix}$$
 $\lambda = 1 \longrightarrow \omega_3 = \begin{pmatrix} 2 \\ -2 \\ 1 \end{pmatrix}$

$$\lambda = 1 \longrightarrow \omega_3 = \begin{pmatrix} 2 \\ -1 \\ 2 \end{pmatrix}$$

 $\omega_1 \cdot \omega_2 = \begin{pmatrix} 2 \\ 2 \end{pmatrix} \cdot \begin{pmatrix} -2 \\ -2 \end{pmatrix} = 0$ $\omega^3 = \begin{pmatrix} 5 \\ -5 \\ -5 \end{pmatrix} = 0$ $\omega_1, \, \omega_2 = \left(\frac{5}{5}\right) \cdot \left(\frac{5}{5}\right) = 0$

So {w, we, w, } is an orthogonal eigenbasis.

To make it orthonormal, you have to divide by the lengths to make then unit vectors:

$$\sim 3 \left\{ \frac{1}{3} \left(\frac{2}{5} \right), \frac{1}{3} \left(\frac{2}{5} \right) \right\}$$

is an orthonormal eigenbosis.

Matrix form:

$$S = QDQ^{-1} \quad \text{for} \quad Q = \frac{1}{3} \begin{pmatrix} 1 & -\frac{3}{2} & \frac{3}{2} \\ \frac{3}{2} & \frac{7}{2} & \frac{3}{2} \end{pmatrix}$$

$$= QDQ^{-1} \quad D = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 2 \end{pmatrix}$$

Recall: A square matrix Q with orthonormal columns T called orthogonal. Then $Q^TQ = I_n \implies Q^T = Q^{-1}$.

Spectral Theorem: A real symmetric matrix S
has an orthonormal eigenbasis of real eigenvectors:

S = QDQT

for an orthogonal matrix Q and a dragonal matrix D.

Eg:
$$S = \begin{pmatrix} -1 & 1 & 2 \\ 1 & -1 & 2 \\ 2 & 2 & 2 \end{pmatrix}$$
 $\rho(\lambda) = -(\lambda - 4)(\lambda + 2)^2$

Eigenspaces:

$$7=4 \Rightarrow Span \{(\frac{1}{2})\}$$

$$7=2 \Rightarrow Span \{(\frac{1}{6}), (\frac{3}{6})\}$$

$$Check: (\frac{1}{2}) \cdot (\frac{7}{6}) = 0 \quad (\frac{1}{2}) \cdot (\frac{7}{6}) = 0$$

$$(\frac{7}{6}) \cdot (\frac{7}{6}) = 2 \neq 0$$

That's ok - (3) and (3) have the same eigenvalue.

So how do we produce an orthonormal eigenbasis? Have to use Gran-Schmidt to find an orthonormal basis of the -2-eigenspace.

$$\omega_1 = \begin{pmatrix} 1 \\ 1 \\ 2 \end{pmatrix} \\
 \omega_2 = \begin{pmatrix} -2 \\ 0 \\ 1 \end{pmatrix} - \begin{pmatrix} -2 \\ 0 \\ 1 \end{pmatrix} - \begin{pmatrix} -1 \\ 0 \\ 0 \end{pmatrix} - \begin{pmatrix} -1 \\ 0 \\ 0 \end{pmatrix} \\
 = \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix} - \begin{pmatrix} -1 \\ 0 \\ 0 \end{pmatrix} - \begin{pmatrix} -1 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} -1 \\ -1 \\ 1 \end{pmatrix}$$

Check:
$$(-1) \cdot (-1) = 0$$
 $(-1) - (1) = 0$

$$S_{0} = \left\{ \frac{1}{16} \left(\frac{1}{2} \right), \frac{1}{12} \left(\frac{1}{6} \right), \frac{1}{18} \left(\frac{1}{1} \right) \right\}$$
 is an

orthonormal eigenbasis, and S=QDQT for

$$Q = \begin{pmatrix} 1/\sqrt{6} & -1/\sqrt{2} & -1/\sqrt{3} \\ 1/\sqrt{6} & 1/\sqrt{2} & -1/\sqrt{3} \\ 2/\sqrt{6} & 0 & 1/\sqrt{3} \end{pmatrix} \qquad D = \begin{pmatrix} 4 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & -2 \end{pmatrix}$$

Procedure to Orthogonally Diagonalize a Real Symmetric Matrix S:

- (1) Dragonalize S. (it is automatically diagonalizable)
- (2) Normalize your eigenvectors/run Gram-Schmidt if GM(2) ≥ 2.
- (3) Put them together -> orthonormal eigenbasis!

The picture is the same as before, but it's easier to visualize multiplying by the orthogonal matrix Q (it preserves lengths & angles).

Exercise (outer product form):

If $\{u_1,...,u_n\}$ is an orthonormal eigenbasis of S and $Su_i = \lambda_i u_i$, so $S = QDQ^{\dagger}$ for $Q = \begin{pmatrix} u_1 ... u_n \end{pmatrix}$ $D = \begin{pmatrix} \lambda_1 ... u_n \end{pmatrix}$ then

Compare: if P_{V} is a prejection matrix, you can write $P_{V} = QQT$ for $Q = (u_{i}, ..., u_{n})$ ded_m(V).

When $P_{V} = u_{i}u_{i}T + ... + u_{n}u_{n}T$.

(This is a special case: $\lambda_{i} = ... = \lambda_{n} = 1$ and $\lambda_{i+1} = ... = \lambda_{n} = 0$).

Positive-Definite Symmetric Matrices

Recall: S=ATA is a very important example of a symmetric matrix!

Observation: If λ is an eigenvalue of S=ATA with eigenvector ν then

v. Sv = v. >v= > ||v||2

 $V \cdot S_{vz} V^{T} S_{vz} = V^{T} A^{T} A_{vz} = (A_{v})^{T} (A_{v})$ $= (A_{v}) \cdot (A_{v}) = ||A_{v}||^{2}$

111112 = 11AV12

Consequence: If λ is an eigenvalue of S=ATA

then $\lambda \ge 0$. Moreover, $\lambda = 0 \Longrightarrow \|Av\| = 0$ $\Longleftrightarrow v \in Nul(A)$, so if A has full column rank
then $\lambda \ge 0$.

Thus ATA has only positive eigenvalues when A has full column rank. This condition is so important that it has a name.

Eg:
$$Q(\frac{3}{0}, \frac{2}{2})QT$$
 is positive-definite.
 $Q(\frac{3}{0}, \frac{2}{2})QT$ is positive-semidefinite.

Positive-definiteness is an important condition. We really want to be able to check it without computing eigenvalues.

Criteria for Positive - Definiteness:
Let S be a symmetric matrix.
The following are equivalent:
(1) S is positive-definite
(2) xT5x>0 for all x \$0 ("positive energy
13) The determinants of all a upper-left
submatrices are positive:
$5 = \begin{pmatrix} 7 & 2 & 0 \\ 2 & 6 & 2 \\ 0 & 2 & 5 \end{pmatrix} \rightarrow 3 \det \begin{pmatrix} 7 & 2 & 0 \\ 2 & 6 & 2 \\ 0 & 2 & 5 \end{pmatrix} > 0$
$det \begin{pmatrix} 7 & 2 \\ 2 & 6 \end{pmatrix} > 0$
det (7) > 0
(4) S=ATA for a matrix A with
full column rank
(5) S has an LN decomposition where
U has positive diagonal entries. (no now swaps needed!)

(5) is fastest: its an elimination problem.

Remarks:

(2) In physics, XTSX sometimes measures the energy of a system.

In any case, if v is an eigenvector with eigenvalue & then

VTSv= v. Xv= 2 ||v||2

50 (2) ⇒> >> >> Dor all >>, 50 (2) ⇒(1).

Conversely (1)=)(2) because if x ≠0 then $Q^Tx \neq 0$, so if $Q^Tx = \begin{pmatrix} 91 \\ 9n \end{pmatrix}$ then

 $x^TSx = x^TQDQ^Tx = (Q^Tx)^TD(Q^Tx)$

 $= (y_1 - y_n) \begin{pmatrix} \lambda_1 \\ \lambda_n \end{pmatrix} \begin{pmatrix} \lambda_1 \\ \lambda_n \end{pmatrix}$

= 1/4/2+ -- + 1/4/2 >0.

(3) Determinants are magic.

(4) (4) ⇒(1): we did this above.

(1) => (4): This is the Cholesky decomposition?

next time

(5) This is the LDL decomposition: next time.

Criteria for Positive - Semidefiniteness:

Let S be a symmetric matrix.

The following are equivalent:

(1) S is positive - semidefinite

(2) xTSx > 0 for all x ≠ 0

13) The determinants of all a upper-left submatrices are nonnegative.

(4) S=ATA for a matrix A

Consequence: II A is any matrix then ATA is positive semidefinite. In particular, it has nonnegative eigenvalues.
