Quadratic Optimization: Variant Lost time: we discussed Sinding the extremal (mind max) values of a quadratic form  $q(x) = \sum_{i} a_{ij} X_i X_j$ subject to the constraint  $|=||x||^2 = x_1^2 + \dots + x_n^2$ . Subject to the Procedure:  $q(x) = x^2 Sx$  for S symmetric orthogonality dissonalize:  $S = QDQ^T D = \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_n \end{pmatrix}$ thanke variables: x = Qy  $\lambda_1 \ge \lambda_2 \ge -\infty \ge \lambda_n$  $\Rightarrow q(x) = \lambda y_1^2 + \dots + \lambda y_n^2$ Answeri maximum =  $\lambda_{r}$ , achieved at any unit  $\lambda_{r}$ -eigenvector maximum =  $\lambda_{r}$ , achieved at any unit  $\lambda_{r}$ -eigenvector Here's an (almost) equivalent variant of this problem that you can draw. Quadratiz Optimization Problem, Variant: Given a quadrator from q(x), find the minimum & maximum values of 1x12 subject to q(x)=1

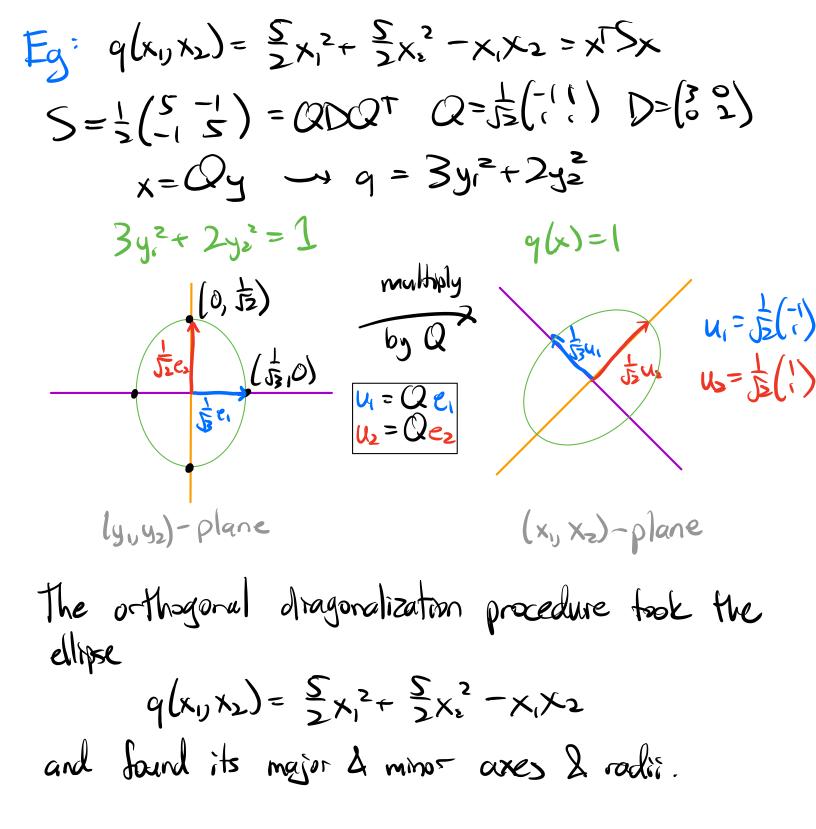

So we switched the function were extremizing  $(||x||^2)$  and the constraint (q|x|=1). In general the min/max may not exist. •  $q(x_{1}, x_{2}) = -x_{1}^{2} - 2x_{2}^{2}$ there is no  $\times$  such that q(x)=1!x2 q(x)=1 • q(x,,x2)= x,2-x22: (C, JC<sup>2</sup>-1<sup>'</sup>) there is no maximum IXI2 subject to g(x)=1: ×,  $q(C, \sqrt{C^2-1}) = 1$ for any (huge) C. Publem' g(x) may be O or negative! Des: A quadratiz form is positive-definite if q(k)>0 for all x+0. NB: If q(x)=x<sup>T</sup>Sx then q is positive-definite S is positive-definite: this is the positiveenergy criterion.

In this case, the problem is equivalent to the  
previous one, as follows:  
Recall: 
$$q(cx) = c^2 q(x)$$
  
Fact: If  $q$  is positive -definite then  
U maximizes  $q(u)$   
subject to  $\|u\| = 1$   
with maximum  
redue  $\lambda_1$   
U minimizes  $q(u)$   
subject to  $\|u\| = 1$   
with minimum  
redue  $\lambda_1$   
 $x = J_{\lambda_1} u$  minimizes  
 $q(x) = q(u)$   
subject to  $\|u\| = 1$   
with minimum  
redue  $\lambda_n$   
 $x = J_{\lambda_1} u$  maximum  
redue  $\lambda_1$   
 $x = J_{\lambda_1} u$  maximizes  
 $q(x) = q(u)$   
 $x = J_{\lambda_1} u$  maximum  
redue  $\lambda_n$   
 $y = \frac{1}{2} \int_{\lambda_1} u$  maximum  
redue  $\lambda_n$   
 $y = \frac{1}{2} \int_{\lambda_1} u$  then  
 $q(x) = q(J_{\lambda_1} u) = \frac{1}{2} \int_{\lambda_1} u$  then  
 $q(x) = q(J_{\lambda_1} u) = \frac{1}{2} \int_{\lambda_1} u$  then  
 $q(x) = q(J_{\lambda_1} u) = \frac{1}{2} \int_{\lambda_1} u$  is minimized  
and ricc-ressq.

So we know exactly how to solve this QO problem  
Voriant: do the same procedure as in the original  
QO problem, and take reciprocols.  
E: Extremize 
$$\|x\|^2$$
 subject to  
 $q(x_1x_2) = \frac{5}{5}x_1^2 + \frac{5}{5}x_2^2 - x_1x_2 = 1$   
Lost three:  $q(x) = xTSx$   
 $S = \frac{1}{5}\begin{pmatrix} 5 & -1 \\ -1 & 5 \end{pmatrix} = QDQT$   $Q = \frac{1}{55}\begin{pmatrix} 7 & 1 \\ 1 & 5 \end{pmatrix} D = \begin{pmatrix} 5 & 2 \\ 5 & 2 \end{pmatrix}$   
 $\circ q$  is moscimized (subject to  $\||x||^2 = 1$ )  
 $\circ t u_1^2 = \frac{1}{52}\begin{pmatrix} 7 & 1 \\ -1 & 5 \end{pmatrix} = QDQT$   $Q = \frac{1}{55}\begin{pmatrix} 7 & 1 \\ 1 & 5 \end{pmatrix} D = \begin{pmatrix} 5 & 2 \\ 5 & 2 \end{pmatrix}$   
 $\circ q$  is moscimized (subject to  $\||x||^2 = 1$ )  
 $\circ t u_1^2 = \frac{1}{52}\begin{pmatrix} 7 & 1 \\ -1 & 5 \end{pmatrix} = QDQT$   $Q = \frac{1}{55}\begin{pmatrix} 7 & 1 \\ 1 & 5 \end{pmatrix} D = \begin{pmatrix} 5 & 2 \\ 5 & 2 \end{pmatrix}$   
 $\circ q$  is moscimized (subject to  $\||x||^2$  subject to  $\|x_1\|^2 = \frac{1}{3}$   
The minimum value of  $\||x||^2$  subject to  $q(x) = 1$   
 $is$   $\frac{1}{3}$ . If is achieved at  $x_1 = \frac{1}{5}u_1$ .  
 $q(u_1) = \sum x_1 = \frac{1}{52}u_2 \Longrightarrow q(x_2) = 1$   $\||x_1\|^2 = \frac{1}{3}$   
The maximum value of  $\||x||^2$  subject to  $q(x) = 1$   
 $is$   $\frac{1}{2}$ . If is achieved of  $x_2 = \frac{1}{5}u_2$ .  
 $\rightarrow v_0 = \frac{1}{5} > \frac{1}{3}$ .

beametric Interpretation Recall: An equation of the form  $\lambda_1 \chi_1^2 + \lambda_2 \chi_2^2 = 1 \qquad (-\frac{1}{\sqrt{3}}, 0) \qquad (\frac{1}{\sqrt{3}}, 0)$ (2,=2,2>0) defines an ellipse. minor (0,-1) (This is a circle horizontally stretched by 1/SR. & vertically stretched by 1/SR.) If q(x, x) = 7,x2+ 2,x2 is dragonal & positive definite then q(x,x2)=1 defines the ellipse above, and extremizing ||x||= I subject to q(x)=1 amounts to finding the shortest (±x) & longest (±y)  $|x|^{2} = 1/\lambda_{1}$ rectors on the ellipse.  $|y|^2 = 1/\lambda_2$ In general,  $q(x) = \lambda_1 x_1^2 + \cdots + \lambda_n x_n^2$  (all  $\lambda_1 > 0$ ) defines an ellipsoid ("egg"); extremizing IIXI2 subject to q(x)=1 means finding the shortest 8 longest vectors.

Non-diagonal case: q(x)=xTSx for S positive-definite. Let  $\lambda \ge \lambda_2 > 0$  be the eigenvalues,  $u_1, u_2$  orthonormal eigenvectors. Change variables: X=Qy Q=(4, 4) q(x)=1 $\lambda_i y_i^2 + \lambda_2 y_2^2 = 1$ (0, J.) multiply (CINC) byQ  $\frac{U_1 = Q_{e_1}}{U_2} = Q_{e_2}$ lyuy2)-plane (x, x2)-plane Upshot: q(x)=1 defines a (rotated) ellipse. The minor axis is in the u,-direction. -> The shortest vectors are the un The major axis is in the uz-direction. - The longest vectors are the uz. So ve're drawn a picture of quadratic optimization problem (variant). Everything works in higher dimensions; just get rotated ellipsoids.

Additional Constraints

These come up naturally in practice (see the spectral graph theory problem on HW13) and in the PCA.

"Second-largest" value: Suppose qlx) is maximized (subject to IIxII=1) at U.. What is the maximum value of qlx) subject to I|x||=1 and x L U.?

This rules out the maximum value -> yet "second largest" value.

How to solve this? • Write q(x) = x<sup>T</sup>Sx • Orthogonally diagonalize S= QDQT Suppose u, is the first column of Q (1<sup>H</sup> λ,-eigenvec) • Set x=Qy us q = λiyi<sup>2</sup> + ... + λnyn<sup>2</sup> λi=λz=...=>λn Answer: The maximum value of qbx) subject to I|x|1=1 & x+u, is λz. It is achieved at any unit λz-eigenvector us that is Lu.

NB: If 
$$\lambda_1 > \lambda_2$$
 then  $u_2 \perp U_1$  automotically.  
Why?  
• If  $q = \lambda_1 y^2 + \dots + \lambda_n y_n^2$  is diagonal then  
 $u_1 = e_1 = (1, 9)_n$  so  $x \perp u_1$  means  $y_1 = 0$   
 $u_2$  extremizing  $\lambda_2 y^2 + \lambda_3 y^2 + \dots + \lambda_n y_n^2$ .  
• Otherwise, change variables  $x = Qy$ .  
 $Q$  is orthogonal, so  
 $y \cdot q = 0 \implies 0 = (Qy) \cdot (Qe_1) = x \cdot u_1$   
 $\|y_1\| = 1 \implies 1 = \|Qy\| = \|x\|$   
(relate constraints on  $x \ge q$ )  
Eq: Find the largest and second-largest values of  
 $q(x) = 2x_1^2 + 2x_2^2 + 5x_3^2 + 2xx_2 - 8xx_3 + 8x_3x_3$   
subject to  $x_1^2 + x_3^2 + x_3^2 = 1$ .  
•  $q = x^T Sx$  for  $S = \begin{pmatrix} 2 & 1 & -4 \\ 1 & 2 & 4 \\ -4 & 4 & 5 \end{pmatrix}$   
•  $S = QDQT$  for  
 $Q = \begin{pmatrix} -V_1 E & V_1 & V_1 S \\ V_1 E & V_1 S & -V_1 S \\ 2x_2 E & 0 & 1x_1 S \end{pmatrix}$   $D = \begin{pmatrix} 9 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & -3 \end{pmatrix}$ 

Largest value is q(x)=9 at  $x=\pm \frac{1}{16}(\frac{1}{2})=\pm u_1$ Second-largest value: The maximum value of q(x) subject to  $|x||=1 \ \ x \pm u_1$  is q(x)=3 achieved at  $x=\pm \frac{1}{6}\binom{1}{6}$ This also works for minimizing.

Second-smallest value: Suppose qlx) is minimized (subject to llx11=1) at Un. What is the minimum value of qlx) subject to I|x|1=1 and x\_Un? Answer: The minimum value of qlx) subject to I|x|1=1 & x\_Un is Nmi. It is achieved at any unit Nmi eigenvector Uni that is \_Un. (automatic if Nmi > Nmi) You can keep going: Third-largest value: Suppose q/x) is maximized (subject to 1/x11=1) at u. and q(x) is maximized (subject to ||x||=1 and x-ly.) at Uz. What is the maximum value of 96c) subject to |x|=1 and x L u, and x L uz? NB: This "rules out" the largest & second-largest relues. Answer: The maximum value of qlx) subject to IIXII=1 & x+u, & x+uz is >3. It is achieved at any unit No-eigenvector Us that is LU, and uz. (automatic it  $\lambda_2 > \lambda_3$ ) This also works for the variant problem, except you have to take reciprocals. Et cetera...

Quadratic Optimization for S=ATA This is what we'll use for PCA. Let S = ATA and  $q(x) = x^TSx$ . Then  $q(x) = x^TSx = x^T(ATA)x = (xTAT)(Ax)$  $= (Ax)^T(Ax) = (Ax) \cdot (Ax) = |Ax||^2$ 

$$S = A^T A \implies x^T S_X = ||A \times ||^2$$

In this case, extremizing g(x) subject to ||x||=1 means extremizing ||Axl<sup>2</sup> subject to ||x||=1. Procedure: to extremize ||Ax||<sup>2</sup> subject to ||x||=1: Orthogonally diagonalize S=ATA is orthonormal eigenboss {u.s..., un?, eigenvalues λ, ≥···≥λn. • The largest value is  $\lambda$ , achieved at any unit & - eigenvector U. • The smallest value is  $\lambda_n$ , achieved at any unit & - ergenvector Un. · The second-largest value is is, achieved at any unit  $\lambda_2$ -eigenvector  $u_2 \perp u_1$ . o . etc.

NB: these are eigenvectors/eigenvalues of S=ATA,  
not of A (which need not be square).  
Def: The matrix non of a matrix A is  
NAI = the newimum value of NAXI subject to  
NXII=1.  
So NAI= 
$$\int_{X_1} = |argest eigenvalue of ATA.$$
  
Eg: Compute NAII for  $A = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ .  
 $ATA = \begin{pmatrix} 2 & 3 \\ 2 & 3 \end{pmatrix} p(\lambda) = \lambda^2 - 6\lambda + S = (\lambda - S)(\lambda - 1)$   
the largest eigenvalue is  $\lambda = S$ , so  $|AI| = IS$ .  
Eigenvector:  $\begin{pmatrix} -b \\ a - \lambda \end{pmatrix} = \begin{pmatrix} -2 \\ -2 \end{pmatrix}$   
Unit eigenvector:  $u_1 = \int_{S=1}^{S=1} \begin{pmatrix} -2 \\ -2 \end{pmatrix} = \int_{S=1}^{L} \begin{pmatrix} -1 \\ -1 \end{pmatrix}$   
has length  $\int_{S=1}^{L} \int_{T^2+\lambda^2+3^2+1}^{Z^2} = \int_{S=1}^{TO} = \int_{S}^{TS} \sqrt{12}$
