

Symmetric Matrixes & the Spectral Theorem

Recall: S is symmetric if $S = S^T$ ($\Rightarrow$ square)

Super-important example: the matrix of column dot products
 $S = A^T A$ for any matrix A $[(A^T A)^T = A^T A^{TT} = A^T A]$

Eg: $S = \frac{1}{9} \begin{pmatrix} 5 & -8 & 10 \\ -8 & 11 & 2 \\ 10 & 2 & 2 \end{pmatrix}$

[demo]: what do you notice about the eigenspaces?

Observation 0: for any vectors v and w ,
 $v \cdot (Sw) = v^T Sw = (S^T v)^T w = (Sv)^T w = (Sv) \cdot w$

$$v \cdot (Sw) = (Sv) \cdot w$$

Observation 1:

Eigenvectors of S with different eigenvalues are orthogonal.

Proof: Say $Sv_1 = \lambda_1 v_1$ $Sv_2 = \lambda_2 v_2$ $\lambda_1 \neq \lambda_2$

$$v_1 \cdot (Sv_2) = v_1 \cdot (\lambda_2 v_2) = \lambda_2 v_1 \cdot v_2$$

$$\parallel$$
$$(Sv_1) \cdot v_2 = \lambda_1 v_1 \cdot v_2$$

$$\lambda_1 v_1 \cdot v_2 = \lambda_2 v_1 \cdot v_2 \Rightarrow (\lambda_1 - \lambda_2) v_1 \cdot v_2 = 0$$

$$\stackrel{\lambda_1 \neq \lambda_2}{\Rightarrow} v_1 \cdot v_2 = 0 \quad \checkmark$$

Observation 2:

All eigenvalues of S are **real**.

Proof: Say $Sv = \lambda v$ and λ is not real.

Then $\lambda \neq \bar{\lambda}$. Conjugate eigenvalue: $S\bar{v} = \bar{\lambda}\bar{v}$.

Observation 1 $\Rightarrow v \cdot \bar{v} = 0$. But

$$v = \begin{pmatrix} z_1 \\ \vdots \\ z_n \end{pmatrix} \quad \bar{v} = \begin{pmatrix} \bar{z}_1 \\ \vdots \\ \bar{z}_n \end{pmatrix}$$

$$\begin{aligned} \Rightarrow v \cdot \bar{v} &= z_1 \bar{z}_1 + \dots + z_n \bar{z}_n \\ &= |z_1|^2 + \dots + |z_n|^2 > 0 \end{aligned}$$

So this can't happen. ✓

Fact: If S is symmetric and λ is an eigenvalue, then $AM(\lambda) = GM(\lambda)$.

(The proof requires ideas from abstract linear algebra)

Consequence: S is **diagonalizable** over the **real numbers**! Moreover, there is an **orthonormal eigenbasis**.

Eg: $S = \frac{1}{9} \begin{pmatrix} 5 & -8 & 10 \\ -8 & 11 & 2 \\ 10 & 2 & 2 \end{pmatrix}$ $p(\lambda) = -(\lambda-1)(\lambda+1)(\lambda-2)$

Eigenvectors:

$$\lambda = 1 \leadsto w_1 = \begin{pmatrix} 1 \\ 2 \\ 2 \end{pmatrix}$$

$$\lambda = 2 \leadsto w_3 = \begin{pmatrix} 2 \\ -2 \\ 1 \end{pmatrix}$$

$$\lambda = -1 \leadsto w_2 = \begin{pmatrix} -2 \\ -1 \\ 2 \end{pmatrix}$$

Check:

$$w_1 \cdot w_2 = \begin{pmatrix} 1 \\ 2 \\ 2 \end{pmatrix} \cdot \begin{pmatrix} -2 \\ -1 \\ 2 \end{pmatrix} = 0$$

$$w_1 \cdot w_3 = \begin{pmatrix} 1 \\ 2 \\ 2 \end{pmatrix} \cdot \begin{pmatrix} 2 \\ -2 \\ 1 \end{pmatrix} = 0$$

$$w_2 \cdot w_3 = \begin{pmatrix} -2 \\ -1 \\ 2 \end{pmatrix} \cdot \begin{pmatrix} 2 \\ -2 \\ 1 \end{pmatrix} = 0$$

So $\{w_1, w_2, w_3\}$ is an **orthogonal** eigenbasis. ✓

To make it **orthonormal**, you have to divide by the lengths to make them unit vectors:

$$\|w_1\| = \sqrt{9} = 3 \quad \|w_2\| = 3 \quad \|w_3\| = 3$$

$$\leadsto \left\{ \frac{1}{3} \begin{pmatrix} 1 \\ 2 \\ 2 \end{pmatrix}, \frac{1}{3} \begin{pmatrix} -2 \\ -1 \\ 2 \end{pmatrix}, \frac{1}{3} \begin{pmatrix} 2 \\ -2 \\ 1 \end{pmatrix} \right\}$$

is an orthonormal eigenbasis.

orthogonal
↓

Matrix form:

$$S = Q D Q^{-1}$$

for $Q = \frac{1}{3} \begin{pmatrix} 1 & -2 & 2 \\ 2 & -1 & -2 \\ 2 & 2 & 1 \end{pmatrix}$

$$= Q D Q^T$$

$$D = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 2 \end{pmatrix}$$

Recall: A square matrix Q with orthonormal columns is called orthogonal. Then

$$Q^T Q = I_n \Rightarrow Q^T = Q^{-1}.$$

Spectral Theorem: A real symmetric matrix S has an orthonormal eigenbasis of real eigenvectors:

$$S = Q D Q^T$$

for an orthogonal matrix Q and a diagonal matrix D .

Fast-forward: The SVD is basically the spectral theorem as applied to $S = A^T A$.

Eg: $S = \begin{pmatrix} -1 & 1 & 2 \\ 1 & -1 & 2 \\ 2 & 2 & 2 \end{pmatrix} \quad p(\lambda) = -(\lambda-4)(\lambda+2)^2$

Eigenspaces:

$$\lambda = 4 \rightsquigarrow \text{Span} \left\{ \begin{pmatrix} 1 \\ 1 \\ 2 \end{pmatrix} \right\}$$

$$\lambda = -2 \rightsquigarrow \text{Span} \left\{ \begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}, \begin{pmatrix} -2 \\ 0 \\ 1 \end{pmatrix} \right\}$$

Check: $\begin{pmatrix} 1 \\ 1 \\ 2 \end{pmatrix} \cdot \begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix} = 0 \quad \begin{pmatrix} 1 \\ 1 \\ 2 \end{pmatrix} \cdot \begin{pmatrix} -2 \\ 0 \\ 1 \end{pmatrix} = 0$

$$\begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix} \cdot \begin{pmatrix} -2 \\ 0 \\ 1 \end{pmatrix} = 2 \neq 0!$$

That's ok - $\begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}$ and $\begin{pmatrix} -2 \\ 0 \\ 1 \end{pmatrix}$ have the same eigenvalue.

So how do we produce an **orthonormal** eigenbasis?

Have to use **Gram-Schmidt** to find an orthonormal basis of the $\lambda = -2$ -eigenspace.

$$w_1 = \begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

$$w_2 = \begin{pmatrix} -1 \\ 0 \end{pmatrix}$$

$$w_3 = \begin{pmatrix} -2 \\ 0 \\ 1 \end{pmatrix} - \frac{\begin{pmatrix} -2 \\ 0 \\ 1 \end{pmatrix} \cdot \begin{pmatrix} -1 \\ 0 \end{pmatrix}}{\begin{pmatrix} -1 \\ 0 \end{pmatrix} \cdot \begin{pmatrix} -1 \\ 0 \end{pmatrix}} \begin{pmatrix} -1 \\ 0 \end{pmatrix}$$

$$= \begin{pmatrix} -2 \\ 0 \\ 1 \end{pmatrix} - \frac{2}{2} \begin{pmatrix} -1 \\ 0 \end{pmatrix} = \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}$$

Check: $\begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix} \cdot \begin{pmatrix} -1 \\ 0 \end{pmatrix} = 0$ $\begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix} \cdot \begin{pmatrix} 1 \\ 2 \end{pmatrix} = 0$ ✓

So $\left\{ \frac{1}{\sqrt{6}} \begin{pmatrix} 1 \\ 2 \end{pmatrix}, \frac{1}{\sqrt{2}} \begin{pmatrix} -1 \\ 0 \end{pmatrix}, \frac{1}{\sqrt{3}} \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix} \right\}$ is an orthonormal eigenbasis, and $S = QDQ^T$ for

$$Q = \begin{pmatrix} 1/\sqrt{6} & -1/\sqrt{2} & -1/\sqrt{3} \\ 1/\sqrt{6} & 1/\sqrt{2} & -1/\sqrt{3} \\ 2/\sqrt{6} & 0 & 1/\sqrt{3} \end{pmatrix} \quad D = \begin{pmatrix} 4 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & -2 \end{pmatrix}$$

Procedure to Orthogonally Diagonalize a Real Symmetric Matrix S :

- (1) Diagonalize S . (it is automatically diagonalizable)
- (2) Normalize your eigenvectors / run Gram-Schmidt if $\text{GM}(\lambda) \geq 2$.
- (3) Put them together $\rightarrow$ orthonormal eigenbasis!

Eg: $S = \frac{1}{2} \begin{pmatrix} 5 & -1 \\ -1 & 5 \end{pmatrix}$ $p(\lambda) = \lambda^2 - 5\lambda + 6 = (\lambda - 2)(\lambda - 3)$

$\lambda_1 = 2 \rightarrow w_1 = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 1 \end{pmatrix}$ $\lambda_2 = 3 \rightarrow w_2 = \frac{1}{\sqrt{2}} \begin{pmatrix} -1 \\ 1 \end{pmatrix}$

So $S = QDQ^T$ for $Q = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}$ $D = \begin{pmatrix} 2 & 0 \\ 0 & 3 \end{pmatrix}$

NB: $Q = \begin{pmatrix} \cos(45^\circ) & -\sin(45^\circ) \\ \sin(45^\circ) & \cos(45^\circ) \end{pmatrix}$

So $Qx = (\text{rotate } x \text{ CCW } 45^\circ)$

Picture:

The picture is the same as before, but it's easier to visualize multiplying by the orthogonal matrix Q (it preserves lengths & angles).

Exercise (outer product form):

If $\{u_1, \dots, u_n\}$ is an orthonormal eigenbasis of S and $Su_i = \lambda_i u_i$, so $S = QDQ^T$ for

$$Q = \begin{pmatrix} u_1 & \dots & u_n \end{pmatrix} \quad D = \begin{pmatrix} \lambda_1 & & 0 \\ & \ddots & \\ 0 & & \lambda_n \end{pmatrix}$$

then

$$S = \lambda_1 u_1 u_1^T + \lambda_2 u_2 u_2^T + \dots + \lambda_n u_n u_n^T$$

Compare: if P_V is a projection matrix, you can write $P_V = QQ^T$ for $Q = \begin{pmatrix} u_1 & \dots & u_d \end{pmatrix}$ $d = \dim(V)$.

$$\hookrightarrow P_V = u_1 u_1^T + \dots + u_d u_d^T.$$

(This is a special case: $\lambda_1 = \dots = \lambda_d = 1$ and $\lambda_{d+1} = \dots = \lambda_n = 0$. Recall P_V is symmetric!)

Positive-Definite Symmetric Matrices

Recall: $S = A^T A$ is a **very important** example of a symmetric matrix!

Observation: If λ is an eigenvalue of $S = A^T A$ with eigenvector v then

$$v \cdot Sv = v \cdot \lambda v = \lambda \|v\|^2$$

$$\begin{aligned} v \cdot Sv &= v^T S v = v^T A^T A v = (Av)^T (Av) \\ &= (Av) \cdot (Av) = \|Av\|^2 \end{aligned}$$

$$\lambda \|v\|^2 = \|Av\|^2$$

Consequence: If λ is an eigenvalue of $S = A^T A$ then **$\lambda \geq 0$** . Moreover, $\lambda = 0 \iff \|Av\| = 0$
 $\iff v \in \text{Nul}(A)$, so if A has **full column rank** then **$\lambda > 0$** .

Thus $A^T A$ has only **positive eigenvalues** when A has full column rank. This condition is so important that it has a name.

Def: A symmetric matrix S is called

- **positive-definite** if all its eigenvalues are **positive**.
- **positive-semidefinite** if all its eigenvalues are **non-negative**.

(positive-semidefinite allows $\lambda=0$ as well.)

- **indefinite** if it has positive and negative eigenvalues.

NB: A positive-definite matrix is also positive-semidefinite!
 $\lambda > 0 \Rightarrow \lambda \geq 0$

Fast-forward: This will be important for solving **quadratic optimization** problems (next week).

- Eg:
- $Q \begin{pmatrix} 3 & 0 \\ 0 & 2 \end{pmatrix} Q^T$ is **positive-definite**
 - $Q \begin{pmatrix} 3 & 0 \\ 0 & 0 \end{pmatrix} Q^T$ is **positive-semidefinite**
 - $Q \begin{pmatrix} 3 & 0 \\ 0 & -2 \end{pmatrix} Q^T$ is **indefinite**.

Positive-definiteness is an important condition. We really want to be able to check it without computing eigenvalues.

Criteria for Positive-Definiteness:

Let S be a symmetric matrix.

The Following Are Equivalent:

- (1) S is positive-definite
- (2) $x^T S x > 0$ for all $x \neq 0$ ("positive energy")
- (3) The determinants of all n upper-left submatrices are positive:

$$S = \begin{pmatrix} 7 & 2 & 0 \\ 2 & 6 & 2 \\ 0 & 2 & 5 \end{pmatrix} \rightarrow \det \begin{pmatrix} 7 & 2 & 0 \\ 2 & 6 & 2 \\ 0 & 2 & 5 \end{pmatrix} > 0$$

$$\det \begin{pmatrix} 7 & 2 \\ 2 & 6 \end{pmatrix} > 0$$

$$\det (7) > 0$$

- (4) $S = A^T A$ for a matrix A with full column rank

- (5) S has an LU decomposition where U has positive diagonal entries.
(no row swaps needed!)

(5) is fastest: it's an elimination problem.

Remarks:

(2) In physics, $x^T S x$ sometimes measures the **energy** of a system.

In any case, if v is an eigenvector with eigenvalue λ then

$$v^T S v = v \cdot \lambda v = \lambda \|v\|^2$$

so $(2) \Rightarrow \lambda \geq 0$ for all λ , so $(2) \Rightarrow (1)$.

Conversely, $(1) \Rightarrow (2)$ because if $x \neq 0$ then $Q^T x \neq 0$, so if $Q^T x = \begin{pmatrix} y_1 \\ \vdots \\ y_n \end{pmatrix}$ then

$$x^T S x = x^T Q D Q^T x = (Q^T x)^T D (Q^T x)$$

$$= (y_1 \dots y_n) \begin{pmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_n \end{pmatrix} \begin{pmatrix} y_1 \\ \vdots \\ y_n \end{pmatrix}$$

$$= \lambda_1 y_1^2 + \dots + \lambda_n y_n^2 \geq 0.$$

(3) Determinants are **magic**.

(Also see the LDLT supplement.)

(4) $(4) \Rightarrow (1)$: we did this above.

$(1) \Rightarrow (4)$: This is the **Cholesky decomposition**:
next time

(5) This is the **LDLT** decomposition: next time.

Criteria for Positive-Semidefiniteness:

Let S be a symmetric matrix.

The following are equivalent:

(1) S is positive-semidefinite

(2) $x^T S x \geq 0$ for all $x \neq 0$

(3) The determinants of all n upper-left submatrices are nonnegative.

(4) $S = A^T A$ for a matrix A
~~with full column rank~~

Consequence: If A is any matrix then $A^T A$ is positive-semidefinite. In particular, it has nonnegative eigenvalues.
