Quadratic Optimization: Variant values of a quadrate form  $q(x) = \sum_{i=1}^{n} a_{ij} X_{i} X_{j}$ subject to the constraint |=||x||2=xi2+--+xn2. Procedure:  $g(x) = x^{T}Sx$  for S symmetric orthogonally diagonalize:  $S = QDQ^{T}D = \begin{pmatrix} \lambda_{1} & 0 \\ 0 & \lambda_{n} \end{pmatrix}$  change variables: x = QQ $\Rightarrow q(x) = \lambda y_1^2 + \dots + \lambda_n y_n^2$ Answeri maximum =  $\lambda_1$ , achieved at any unit  $\lambda_1$ -eigenvector maximum =  $\lambda_n$ , achieved at any unit  $\lambda_n$ -eigenvector Here's an (almost) equivalent ranant of this problem that you can draw. Quadratiz Optimization Problem, Variant: Given a quadrator form q(x), find the minimum & maximum values of IXI subject to q(x)=1. So we switched the function were extremizing (11×112) and the constraint (9W=1).

q(x)=1: this is a level set of the function q(x) Extremizing IIxII2 just means finding the shortest & largest vectors on this level set. Bad Eg: 9 (x, x2)= x,2-x2=1 detines a hyperbola -> Shortest vectors are (1,0) and (-1,0) So the minimum value of IXI2

B | \pm (1.0) | \frac{2}{5} | . -> there is no maximum IXIE subject to q(x)=1: there are arbitrarily long vectors on the hyperbola.

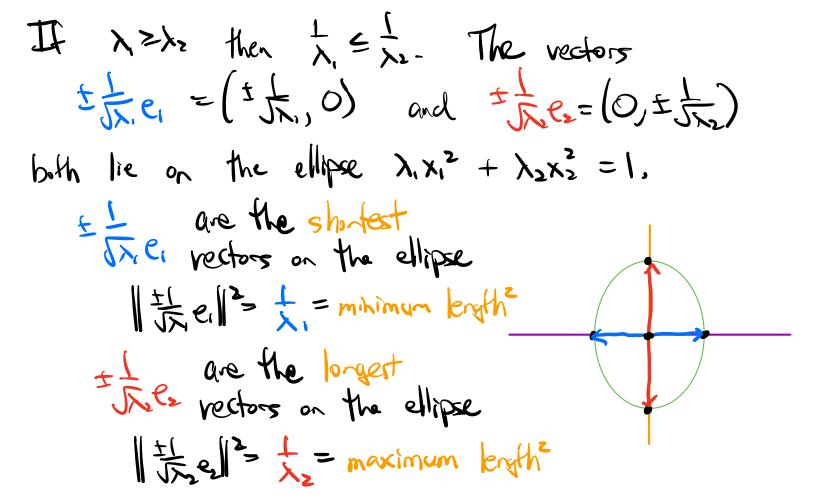

How to draw this problem?

Good Eg: An equation of the form main (0, the)  $\lambda_1 \times \lambda_2^2 + \lambda_2 \times \lambda_3^2 = 1$ ( $\lambda_2 \lambda_2 > 0$ )

( $\lambda_3 \lambda_4 > 0$ )

( $\lambda_4 \lambda_5 > 0$ )

( $\lambda_5 \lambda_5$ 

In general,  $q(x) = \lambda_1 x_1^2 + \cdots + \lambda_n x_n^2$  (all  $\lambda_1 > 0$ ) defines an ellipsoid ("egg"); extremizing lixil" subject to q(x) = 1 means finding the shortest 2 largest vectors.

•

are the shortest

The rectors on the ellipsoid

I the ell's the minimum length?

The are the longest

The rectors on the ellipsoid

I the ell's the maximum length?

What if all Is not diagonal?

We still need the condition "All hiso"—otherwise a min or max may not exist.

Def: A quadratiz form is positive-definite if  $q(\omega)>0$  for all  $x\neq0$ .

NB: If q(x)=xTSx then

q is positive-definite > 5 is positive-definite

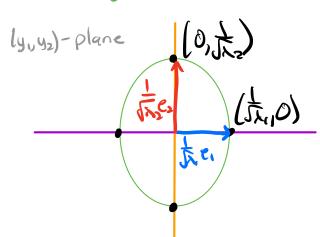

This is the positive energy criterion.

Suppose that qui=xTSx is positive-definite.

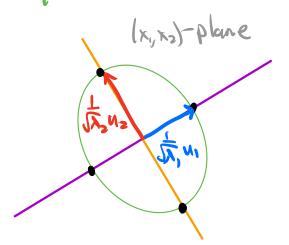

Let  $\lambda_1 \ge \lambda_2 > 0$  be the eigenvalues of S and  $u_1, u_2$  orthonormal eigenvectors

Change variables: x=Qy Q=(1, 1/2)

$$q(x)=1$$

by Q

Upshot: If q is positive-definite, then q(x)=1 defines a (rotated) ellipse. The minor exis is in the u,-direction. -> The shortest vectors are to un The major axis is in the uz-direction. - The longest vectors are thus. Orthogonally diagonalizing S=QDQT found the major L'impor axes 2 radii! Eg:  $q(x_1, x_2) = \sum_{i=1}^{n} x_i^2 + \sum_{i=1}^{n} x_i^2 - x_i x_2 = x^T > x$  $S = \frac{1}{5} \begin{pmatrix} 5 & -1 \\ -1 & 5 \end{pmatrix} = QDQ^T Q = \frac{1}{5} \begin{pmatrix} -(1) \\ 1 & 1 \end{pmatrix} D = \begin{pmatrix} 3 & 2 \\ 0 & 2 \end{pmatrix}$  $x = Qy \rightarrow q = 3y_1^2 + 2y_2^2$ 3y2+ 2y2=1 9(x)=1 multiply (0, 克)  $u_{i} = \int_{\Sigma} \left( \frac{1}{i} \right)$   $u_{i} = \int_{\Sigma} \left( \frac{1}{i} \right)$ by Q 5 e, (5,0) 4 = Q e, 4 = Qe2

lyuyz)-plane (xy xz)-plane

Shortest rectors: 
$$\pm \frac{1}{13}u_1 = \pm \frac{1}{15}(\frac{1}{1})$$
 length<sup>2</sup>=  $\frac{1}{3}$  longest vectors:  $\pm \frac{1}{3}u_2 = \pm \frac{1}{3}(\frac{1}{1})$  length<sup>2</sup>= $\frac{1}{3}$  length<sup>2</sup>= $\frac{1}{3}$ 

The orthogonal diagonalization procedure took the ellipse

$$q(x_1, x_2) = \frac{5}{2}x_1^2 + \frac{5}{2}x_2^2 - x_1x_2$$

and found its major 4 minor exes 2 radii: the change of variables

$$x = Qy = \frac{1}{12} \left( -\frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_1 = \frac{1}{12} \left( -\frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_2 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_3 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{1}{12} \right) \left( \frac{91}{92} \right) \sim x_4 = \frac{1}{12} \left( \frac{91}{92} \right) \sim x_4 = \frac{$$

made q(x)=1 who the standard (non-votated) ellipse  $3y_i^2 + 2y_z^2 = 1$ .

## Relationship to the original QO problem:

How is this "almost equivalent" to extremizing qbd subject to

## Fact: If q is positive -definite then

u maximizes q(u) subject to ||w|| = 1with maximum value 7,

 $x = \int_{X}^{L} u$  minimizes (=) IXI's subject to

q(x)=1 with minimum

value 1/x.

and

u minimizes qua) subject to IW=1 with minimum value In

x=Jhu maximizes

[XIII subject to

q(x)=1 with maximum

value 1/hn

if  $q(u) = \lambda > 0$  and  $x = \sqrt{\frac{1}{2}}u$  then  $\|x\|^2 = \frac{1}{\lambda}$  $q(x) = q(\pm u) = \pm q(u) = \frac{1}{\lambda} \cdot \lambda = 1.$ If  $\lambda \gg \text{maximized then } \|\lambda\|^2 = \frac{1}{\lambda} \approx \text{minimized}$  and vice-versa.

So the QO variant gles us a picture of the original QO problem, at least when 9 is positivedefinite— we're just finding axes & radii of ellipsoids

## Additional Constraints

These come up naturally in practice (see the spectral graph theory problem on the HW) and in the PCA.

"Second-largest value:

Suppose q/x) is maximized (subject to 11x11=1) at u. What is the maximum value of q/x) subject to 11x11=1 and x L u.?

This rules out the maximum value >> get "secondlargest" value.

How to solve this?

- · Write q(x) = xTSx
- · Orthogonally diagonalize S= QDQT Suppose u, is the first column of Q (1st x,-eigenvec)
- Set x=Qy $y=\lambda_1y_1^2+\cdots+\lambda_ny_n^2$   $\lambda_1\geq\lambda_2\geq\cdots\geq\lambda_n$

Answer: The maximum value of qlx) subject to  $||x|| = ||2|x \perp u_1|| \ge \lambda_2$ . It is achieved at any unit  $\lambda_2$ -eigenvector us that is  $\perp u_1$ .

NB: If x,> xz then uz Lu, automatically.

Why?

• If 
$$q = \lambda_1 y_1^2 + \cdots + \lambda_n y_n^2$$
 is diagonal then  $u_1 = e_1 = (1, s_1, \ldots)$  so  $x + u_1$  means  $y_1 = 0$  as extremizing  $\lambda_2 y_2^2 + \lambda_3 y_3^2 + \cdots + \lambda_n y_n^2$ .

· Otherwise, charge variables x=Qy.

Q is orthogonal, so

$$y \cdot q = 0 \implies 0 = (Qy) \cdot (Qe_i) = x \cdot \alpha_i$$
 $||y|| = 1 \implies 1 = ||Qy|| = ||x||$ 

(relate constraints on  $x & y = 0$ )

Eg: Find the largest and second-largest values of  $q(x) = 2x_1^2 + 2x_2^2 + 5x_3^2 + 2x_1x_2 - 8x_1x_3 + 8x_2x_3$  subject to  $x_1^2 + x_2^2 + x_3^2 = 1$ .

• 
$$q = x^T S_X$$
 for  $S = \begin{pmatrix} 2 & 1 & -4 \\ 1 & 2 & 4 \\ -4 & 4 & 5 \end{pmatrix}$ 

· Sz QDQT for

$$Q = \begin{pmatrix} -1/16 & 1/13 & 1/13 \\ 1/16 & 1/13 & 1/13 \\ 2/16 & 0 & 1/13 \end{pmatrix} \qquad D = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & -3 \end{pmatrix}$$

Largest value is q(x)=9 at x=1 is  $(\frac{1}{2})=\pm u_1$ Second-largest value: The maximum value of q(x) subject to |x||=1 &  $x\perp u_1$  is q(x)=3 achieved at  $x=\pm\frac{1}{6}(\frac{1}{6})$ 

This also works for minimizing.

Second-smallest value:

Suppose qlx) is minimized (subject to ||x||=1) at un. What is the minimum value of qlx) subject to ||x||=1 and x Lun?

 You can keep going:

Third-largest value:

Suppose qlx) is maximized (subject to ||x||=1) at u, and qlx) is maximized (subject to ||x||=1 and xLu,) at uz.

What is the maximum value of 9(x) subject to |x|=1 and x Lu, and x Lu,?

NB: This "rules out" the largest & second-largest ralues.

Answer: The maximum value of qlx) subject to  $||x|| = ||A| \times ||$ 

(automatic it \(\lambda\_2 > \lambda\_3\)

This also works for the variant problem, except you have to take reciprocals

Et cetera...

Quadrata Optimization for S=ATAThis is what we'll use for PCA. Let S=ATA and q(x)=xTSx. Then q(x)=xTSx=xT(ATA)x=(xTAT)(Ax)  $=(Ax)T(Ax)=(Ax)\cdot(Ax)=|Ax||^2$ 

qW= |ANI2 is a quadratic form with S=ATA

In this case, extremizing qw subject to ||x||=1 means extremizing  $||Ax||^2$  subject to ||x||=1.

Procedure: to extremize  $||Ax||^2$  subject to ||x||=1:
Orthogonally diagonalize S=ATA

- The largest value is  $\lambda_1$ , achieved at any unit  $\lambda_1$  eigenvector  $u_i$ .
- The smallest value is  $\lambda_n$ , achieved at any unit  $\lambda_n$  eigenvector  $u_n$ .
- · The second-largest value is λ2, achieved at any unit λ2-eigenvector u2 Lu...... etc.

NB: these are eigenvectors/eigenvalues of S-ATA, not of A (which need not be square). Def the matrix non of a matrix A is |A| = the neximum value of |Axl subject to |XI = 1. So MH= Jx,  $\lambda_1 = |argest|$  eigenvalue of ATA. Eg: Compute IAII for A= ( ).  $FA = \begin{pmatrix} 3 & 2 \\ 2 & 3 \end{pmatrix}$   $p(\lambda) = \lambda^2 - 6\lambda + 5 = (\lambda - 5)(\lambda - 1)$ The largest eigenvalue is  $\lambda = 5$ , so  $\|A\| = 15$ . Eigenvector:  $\begin{pmatrix} -b \\ a-\lambda \end{pmatrix} = \begin{pmatrix} -2 \\ -2 \end{pmatrix}$ Unit eigenvector:  $u_1 = \sqrt{\frac{2}{12}} \left( \frac{2}{-2} \right) = \sqrt{\frac{2}{12}} \left( \frac{-2}{-2} \right) = \sqrt{\frac{1}{2}} \left( \frac{-2}{-1} \right)$ Check  $Au_1 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \cdot \frac{1}{12} \begin{pmatrix} -1 \\ -1 \end{pmatrix} = \frac{1}{12} \begin{pmatrix} -\frac{1}{12} \\ -\frac{1}{12} \end{pmatrix}$ has length 12.112+22+12 = 15
